# SURVEY REPORT <br> FROM THE JOINT NORWEGIAN/RUSSIAN ACOUSTIC SURVEY OF PELAGIC FISH IN THE BARENTS SEA SEPTEMBER - OCTOBER 2001 

## Synopsis

The survey was carried out in the period $3^{\text {rd }}$ of September to $4^{\text {th }}$ of October 2001 and was terminated by a meeting in Vadsø 5-7th October. Four research vessels participated in the survey:

| Vessel | Institute | Cruise leader | Date |
| :---: | :---: | :---: | :---: |
| "Johan Hjort" | IMR, Bergen | H. Gjøsæter | $10 / 9-4 / 10$ |
| "G.O.Sars" | IMR, Bergen | J.H. Nilsen | $10 / 9-4 / 10$ |
| "AtlantNIRO" | PINRO, Murmansk | D. Prozorkevich | $3 / 9-4 / 10$ |
| "F. Nansen" | PINRO, Murmansk | I. Dolgolenko | $3 / 9-4 / 10$ |

The main aim of the survey was to estimate the sizes of two pelagic fish stocks in the Barents Sea, the capelin and the polar cod, in addition to studying their biology and geographical distribution. An estimate was also made of a third pelagic species in the area, the young herring. The survey on pelagic species formed a part of a multipurpose survey, with aim to study fish, environmental features, and plankton. On "Johan Hjort" acoustic experiments on capelin avoidance towards vessel noise were done.

This report mainly concerns the results on the pelagic fish species, but includes a general description of the hydrographical situation in the area. A list of the scientific members on all vessels is given in Appendix I.

The coverage of the stock of capelin was considered satisfactory.
The capelin stock was estimated at 3.6 million tonnes, 0.8 times the estimate obtained last year. About 2.0 million tonnes were assumed to be maturing.
The polar cod stock was estimated at 1.9 million tonnes, about 1.4 times higher than that measured last year and the highest estimate on record.

The young stages of the Norwegian Spring Spawning Herring were partly covered during the survey. About 12000 tonnes of one-year-olds, 600000 tonnes of two-year-olds and 160 000 tonnes of three-year-olds were found in the south-eastern parts of the Barents Sea.

In the south-western parts of the Barents Sea young blue whiting were observed in considerable amounts, more than $50 \%$ belonged to the 2000 year class. A quantitative estimation was not attempted since only a small area of the total distribution area of this species was covered.

## Methods

The cruise leaders prior to the survey adopted a general plan for the survey. A team consisting of N.G. Ushakov (PINRO) and H. Gjøsæter (IMR) on board "Johan Hjort" conducted a joint leadership over the whole survey. This implied a day-to-day planning of survey grid, assessment of acoustic data from all vessels, calculations of stock sizes for the target species, and preparing of the joint report. "AtlantNIRO" was adopted as "hydrographic vessel", with the responsibility to gather and process all hydrographic data. Data on cruise tracks, hydrography, integrator values etc. were exchanged by use of satellite or radio telex, and these data were used during the day-to-day planning of the survey.

This way of organising the survey enabled the survey leaders to control the day to day coverage of the area and to improve the total coverage by a daily revision of the sailing routes, thus optimising the total outcome of the effort put into the survey.

The survey area was chosen based on general knowledge of the distribution of the target species, and on information about fish distribution from the International 0-group survey preceding the present survey.
"G.O. Sars" and "Johan Hjort" was granted permission to work in a small area in the northern part of Russian EEZ. The two Russian vessels, therefore, had to cover the total Russian EEZ. A relatively good coverage of the total capelin distribution area was obtained.

Survey routes and stations are shown in Fig. 1, 2 and 3. The main distribution area of capelin was surveyed with course lines 15 and 20 nautical miles apart, while most other areas were surveyed with course lines 30 or more nautical miles apart. "AtlantNIRO" and "F. Nansen" surveyed the eastern and central parts of the Barents Sea whereas "Johan Hjort" and "G.O. Sars" surveyed the north-western, central, and western parts. Altogether, 15500 nautical miles of survey tracks were made, about 5\% more than last year.

The two Norwegian vessels worked with EK-500 echo sounders and BEI post processing systems, "AtlantNIRO" and "F. Nansen" used EK-500, "AtlantNIRO" had a BI-500 and "F. Nansen" a SONIS post processing system. Echo intensities were integrated continuously, and mean values per nautical mile were recorded for each fifth nautical mile. The echograms, with their corresponding $\mathrm{s}_{\mathrm{A}}$-values, were scrutinised every day. Contributions from the seabed, false echoes, and noise were deleted, and corrections were made in case of the presence of a bubble layer. The two Norwegian vessels are equipped with transducers on adjustable keels that can be lowered in rough weather to avoid the damping effect of bubbles.

The corrected values for integrated echo intensity were allocated to species according to the trace pattern of the echograms and the composition of the trawl catches. Only data from pelagic trawl hauls and bottom trawl hauls set on registrations extending to the bottom were included in the stock abundance calculations for capelin and polar cod, as only these were considered representative for the pelagic component of the stocks, which is measured acoustically.

The echo sounders were watched continuously, and trawling was carried out whenever the recordings changed their characteristics and/or the need for biological data made it necessary. Trawling was thus carried out both for identification purposes and to obtain biological observations, i.e., length, weight, maturity stage, stomach data, and age. On "Johan Hjort", a "HCL Multisampler", a device attached to a pelagic trawl with three cod ends that can be opened and closed by a signal from the vessel, was used when registrations at various depths were found. In total, 343 trawl hauls were made during the survey.

The vessels gave the $\mathrm{s}_{\mathrm{A}}$-values in absolute terms based on sphere calibrations, that is, as scattering cross section in $\mathrm{m}^{2}$ per square nautical mile. The acoustic equipment of the vessels was calibrated by a standard copper sphere prior to the survey (See Appendix II).

## Computations of stock sizes

The computations of number of individuals and biomass per length-and age group were made using a new stock size estimation program "BEAM" built on SAS GIS and developed at IMR. Stock size estimates were also made by the same computer programme as in previous years for comparison. Both programs have been shown to give identical results when run on historic data. This was also confirmed during the present study, when the capelin estimate was made using both programs. A strata system, dividing the Barents Sea in squares of $1^{\circ}$ (latitude) x $2^{\circ}$ (longitude), was used as basis for the calculation.

Sampling

| Capelin | Norwegian vessels | Russian vessels | Sum |  |  |
| ---: | :---: | :---: | :---: | :---: | :---: |
| No of samples | 144 |  |  |  |  |
| Nos. length measured | 11460 | 100 | 244 |  |  |
| Nos. aged | 6750 | 15318 | 26778 |  |  |
| Polar cod |  |  | 7848 |  |  |
| No of samples | 68 | 83 | 13051 |  |  |
| Nos. length measured | 3451 | 500 | 16502 |  |  |
| Nos. aged | 1118 |  |  |  |  |

## Results and discussion

## Area coverage

The total vessel time this year allocated to the survey was almost equal to that last year. Some working days were lost when "G.O. Sars" returned to port after 1 day to exchange a member of crew and when "Johan Hjort" returned to port when a member of the crew became ill. One day was also lost when "Johan Hjort" lost a trawl but managed to rescue it. Even though the weather conditions were unfavourable during parts of the survey, with several days of wind force above $15 \mathrm{~m} / \mathrm{sec}$, a total coverage of the capelin distribution area was achieved. The present survey, with its east-west transects either 15 or 20 nautical miles apart from $74^{\circ}$ (in western areas) and $69^{\circ}$ (in the eastern) to $80^{\circ}$ is comparable to last year's survey but extends more northerly, and is probably the most complete coverage obtained at any capelin survey in the time series. The new survey design introduced last year and used this year, running eastwest courses starting in the south, proved successful. However, since the northern limit of the capelin distribution seems to be more variable than the southern limit, starting the survey in the north should be considered in the future. "Johan Hjort" had dedicated some working time during the first part of the survey to experimental work (see below). This made that vessel's coverage not synoptic with the other vessels during the first week of work.

## Capelin

## Distribution

The geographical density distribution of the total stock and each age group are shown in Figs. 4 to 8 . The distribution area resembled that found last year, but extended 60-100 nautical miles to the north compared to that in 2000 . Never since 1975 has the northern limit of the capelin distribution during autumn been found so far north, extending north of $80^{\circ} \mathrm{N}$ west of Franz Joseph Land. The extension in the east west direction was equal to that found last year, from the Bear Island in the west to Novaja Zemlja in the east. However, this year larger amounts of capelin were found in the Storfjordrenna area south of Spitsbergen. The main concentration stretched out from about $77^{\circ} 30^{\prime} \mathrm{N}, 34-36^{\circ} \mathrm{E}$ northwards to $79^{\circ} 30^{\prime} \mathrm{N}, 27^{\circ}-37^{\circ} \mathrm{E}$ and up to $80^{\circ} 10^{\prime} \mathrm{N}$ between 41 and $45^{\circ} \mathrm{E}$ (Figure 8). In some areas, mainly to the east of about $38^{\circ} \mathrm{E}$, the capelin was found together with the polar cod, sometimes in mixed concentrations, sometimes separated into distinct layers. In areas where humpback whales were found in dense aggregations (north of $79^{\circ} \mathrm{N}$ ), capelin were found mainly in dense schools near the bottom. Figure 9 shows an example of such registrations in position $79^{\circ} 18^{\prime} \mathrm{N}-33^{\circ} 00^{\prime} \mathrm{E}$. In some areas capelin was found together with polar cod. In such areas, it was difficult to discern between the two types of fish based on the recordings. In Figure 10 is shown an example of such registrations from $78^{\circ} 29^{\prime} \mathrm{N}-38^{\circ} 58^{\prime} \mathrm{E}$, where the species composition was determined by a multisampler haul.

## Abundance estimate and size by age

The mean $\mathrm{s}_{\mathrm{A}}$-value in each basic square was converted to fish area density $\rho_{\mathrm{A}}$ using the relation

$$
\rho_{A}=\frac{s_{A}}{\bar{\sigma}}
$$

and number of fish was found by multiplying with the area of the square. Numbers were converted to biomass by multiplying with observed mean fish weight in each length group.
The target strength relation for capelin is given by:

$$
T S=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=19.1 \cdot \log L-74.0
$$

corresponding to a $\sigma$-value of $\quad 5.00 \cdot 10^{-7} \cdot L^{1.91}$

The results of the estimation are given in the text table below. The 2000 estimate is shown on shaded background for comparison.

| Year class |  | Age | Number (109) |  | Mean weight (g) |  | Biomass ( $\mathbf{1 0}^{\mathbf{3}} \mathbf{t}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 | 1999 | 1 | 113.6 | 449.2 | 3.3 | 3.8 | 374.8 | 1699.7 |
| 1999 | 1998 | 2 | 218.7 | 110.6 | 11.0 | 14.4 | 2401.1 | 1591.8 |
| 1998 | 1997 | 3 | 30.5 | 34.1 | 26.7 | 27.9 | 813.8 | 951.0 |
| 1997 | 1996 | 4 | 1.0 | 0.8 | 35.5 | 37.7 | 37.7 | 29.5 |
| Total stock in |  |  |  |  |  |  |  |  |
| 2001 | 2000 | 1-4 | 363.9 | 594.7 | 10.0 | 7.2 | 3630.0 | 4273.1 |
| Based on TS value: $19.1 \log \mathrm{~L}-74.0$, corresponding to $=5.0 \cdot 10^{-7} \cdot \mathrm{~L}^{1.91}$ |  |  |  |  |  |  |  |  |

Details of the 2001 estimate are shown in Table 1 and the estimates by age group of the capelin stock 1 years old and older from 1973-2001 are shown in Table 2.

The total stock is estimated at about 3.6 million tonnes, about $80 \%$ of the stock estimated last year. About $56 \%$ (2019 thousand tonnes) of this stock is maturing. The 2000 year class (1-group) consists, according to this estimate, of about 114 billion individuals. This estimate is almost one fourth of that obtained for the 1 -group last year. The mean weight is estimated at 3.3 g , which is somewhat lower than that measured last year, and 0.2 g below the long-term average. The biomass of the 2000 year class is about 0.4 million tonnes. It should be kept in mind that, given the limitations of the acoustic method concerning mixed concentrations of small capelin and 0 -group fish and near-surface distribution, the 1 -group estimate might be more uncertain than that for older capelin. However, based on the findings during the 0 -group survey covering the same areas in August, 1 -group capelin were not frequently found mixed with 0 -group in the surface layers this year.

The estimated number of fish in the 1999 year class (2-group) is about 219 billions, two times higher than the 1998 year class measured last year. The mean weight at this age is 11.0 g ( 14.4 g in 2000), and consequently the biomass of the two years old fish is about 2.4 million tonnes. The mean weight is lower than in the seven last years but is above the longterm average (Table 2).

The 1998 year class is estimated at about 30 billion individuals with mean weight 26.7 g , giving a biomass of about 813 thousand tonnes. The mean weight is one of the highest on record and is 10 g above the long-term average mean weight. The 1997 year class (now 4 years old) is estimated at 1.1 billion individuals. With a mean weight of 37.7 g this age group makes up only about 37 thousand tonnes. Practically no capelin older than four years was found.

## Mortality, length-, weight- and age-distributions

The text table below shows the number of fish in the various year classes, and their "surveymortality" from age one to two.

| Year | Year class | Age 1 $\left(10^{9}\right)$ | Age 2 $\left(10^{9}\right)$ | Total mort. \% | Total mort. Z |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $1984-1985$ | 1983 | 154.8 | 48.3 | 69 | 1.16 |
| $1985-1986$ | 1984 | 38.7 | 4.7 | 88 | 2.11 |
| $1986-1987$ | 1985 | 6.0 | 1.7 | 72 | 1.26 |
| $1987-1988$ | 1986 | 37.6 | 28.7 | 24 | 0.27 |
| $1988-1989$ | 1987 | 21.0 | 17.7 | 16 | 0.17 |
| $1899-1990$ | 1988 | 189.2 | 17.6 | 6 | 0.06 |
| $1990-1991$ | 1989 | 700.4 | 580.2 | 17 | 0.19 |
| $1991-1992$ | 1990 | 402.1 | 196.3 | 51 | 0.72 |
| $1992-1993$ | 1991 | 351.3 | 53.4 | 85 | 1.88 |
| $1993-1994$ | 1992 | 2.2 | 3.4 | - | - |
| $1994-1995$ | 1993 | 19.8 | 8.1 | 59 | 0.89 |
| $1995-1996$ | 1994 | 7.1 | 11.5 | - | - |
| $1996-1997$ | 1995 | 81.9 | 39.1 | 52 | 0.74 |
| $1997-1998$ | 1996 | 98.9 | 72.6 | 27 | 0.31 |
| $19988-1999$ | 1997 | 179.0 | 101.5 | 43 | 0.57 |
| $1999-2000$ | 1998 | 155.9 | 110.6 | 29 | 0.34 |
| $2000-2001$ | 1999 | 449.2 | 218.7 | 51 | 0.72 |

As there has been no fishing on these age groups, the figures for total mortality constitute natural mortality only, and probably reflect quite well the predation on capelin. As can be seen from the table, the mortality was high prior to 1988 , but then a substantial decrease occurred in 1988-89, probably caused by a diminished predation pressure from cod. From 1990, the mortality again increased, up to $85 \%$ in 1992-93. This increase is in accordance with the observation of an increasing stock of cod, which were preying on a decreasing stock of capelin. The mortalities calculated for the period 1996-2001 varied between 27 and $52 \%$ and indicate a somewhat lower level of mortality. The results of the calculation for the year classes 1988, 1992, and 1994 show, however, that either the one-group are underestimated or the two-group is overestimated these years. Knowing that the measurement of the 1-group is more uncertain than the older age groups due to limitations in the acoustic method, the first mentioned possibility is the most probable.

Length and age distributions for the various age groups are shown in Fig. 11 (for the subareas used in the stock size estimation) and Fig. 12 (for the total area).

## Polar cod

As in previous years, the coverage of the polar cod distribution is considered incomplete. In some areas, particularly in the northern, a definite boundary of the polar cod distribution area could not be found within the time allocated to the survey. During a Norwegian trawl survey for Greenland halibut during late August-early September in the areas north of Spitsbergen, considerable amounts of polar cod was caught in bottom trawl in the studied areas. This situation is common during the autumn, when the polar cod stock is widely distributed in the northern part of the Barents Sea.

## Distribution

The densest registrations of polar cod were made in the area between $73^{\circ} \mathrm{N}$ and $77^{\circ} \mathrm{N}$, east of $40^{\circ}$ E. Dense occurrences were also extending to coastal waters of Novaja Zemlja south of $72^{\circ} \mathrm{N}$. East, south and west of Spitsbergen dense local concentrations were registered.

## Abundance estimation

The stock abundance estimate by age, number, and weight was calculated using the same computer program as for capelin. Echo densities were converted to absolute numbers using the following TS-relation:

$$
T S=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=21.8 \cdot \log L-72.7
$$

corresponding to a $\sigma$-value of $6.7 \cdot 10^{-7} \cdot L^{2.18}$

A detailed estimate based on this TS relation is given in Table 3, and the main results are summarised in the text table below. The 2000 estimate is shown on a shaded background for comparison.

The total geographical density distribution of polar cod by age is shown in Figs. 1317. Age- and length distribution for the polar cod stock in the subareas used for stock size estimation and for the total area are given in Figs. 18 and 19, respectively.

| Year class |  | Age$1$ | Number (109) |  | Mean weight (g) |  | Biomass ( $10{ }^{\mathbf{3}} \mathrm{t}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 | 1999 |  | 77.1 | 33.8 | 9.2 | 8.0 | 709.0 | 269.4 |
| 1999 | 1998 | 2 | 15.7 | 20.0 | 27.7 | 21.6 | 434.5 | 432.4 |
| 1998 | 1997 | 3 | 12.5 | 14.6 | 47.1 | 40.9 | 589.3 | 597.6 |
| 1997 | 1996 | 4 | 2.3 | 0.8 | 58.2 | 57.6 | 132.1 | 48.4 |
| Total stock in |  |  |  |  |  |  |  |  |
| 2001 | 2000 | 1-5 | 107.7 | 69.2 | 17.4 | 19.5 | 1869.6 | 1347.8 |
| Based on TS value: $21.8 \log \mathrm{~L}-72.7$, corresponding to $\sigma=6.7 \cdot 10^{-7} \cdot \mathrm{~L}^{2.18}$ |  |  |  |  |  |  |  |  |

The 2000 year class (the one-year-olds) is 2.3 times as numerous as the one-group measured last year, and their mean weight is 1.2 gram higher. The biomass is, therefore, 2.6 times larger than that of the one-year-olds measured last year. The size of the 1999 year class (the two-year-olds) is somewhat lower than that of the two-group found last year but with higher mean weight. The biomass is, therefore, equal to that of the 1998 year class estimated last year. The three-years-old fish (1998 year class) is also less numerous than the three-group estimated last year but has a much higher mean weight. Consequently, the biomass of this age group is about equal to that for the corresponding age group during the 2000 survey. The four-year-olds (1997 year class) are scarcely found. The total stock, estimated at 1.9 million tonnes, is almost 1.4 times larger than that estimated last year, and is the highest on record. It should be noted that the area west of Spitsbergen, which contained more than 200000 t of polar cod was not covered last year. In addition, the coverage extended further north to the
east of Spitsbergen this year. Therefore, a part of the increase in the estimate might stem from the increase in area coverage of the stock.

The text tables below show the "survey-mortality rates" of polar cod of the year classes 1984 to 1999.

| Year | Year class | Age $1\left(10^{9}\right)$ | Age 2 $\left(10^{9}\right)$ | Total mort. \% | Total mort Z |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $1986-1987$ | 1985 | 24.0 | 10.1 | 58 | 0.86 |
| $1987-1988$ | 1986 | 15.0 | 1.5 | 90 | 2.30 |
| $1988-1989$ | 1987 | 4.3 | 1.8 | 58 | 0.87 |
| $1989-1990$ | 1988 | 13.5 | 2.2 | 84 | 1.81 |
| $1990-1991$ | 1989 | 3.8 | 4.2 | - | - |
| $1991-1992$ | 1990 | 23.7 | 14.0 | 41 | 0.53 |
| $1992-1993$ | 1991 | 22.9 | 18.9 | 17 | 0.19 |
| $1993-1994$ | 1992 | 16.3 | 9.3 | 43 | 0.56 |
| $1994-1995$ | 1993 | 27.5 | 6.5 | 76 | 1.44 |
| $1995-1996$ | 1994 | 30.7 | 10.1 | 67 | 1.11 |
| $1996-1997$ | 1995 | 19.4 | 7.8 | 59 | 0.91 |
| $1997-1998$ | 1996 | 15.8 | 7.6 | 52 | 0.73 |
| $1998-1999$ | 1997 | 89.9 | 22.8 | 75 | 1.37 |
| $1999-2000$ | 1998 | 59.4 | 20.0 | 66 | 1.09 |
| $2000-2001$ | 1999 | 33.8 | 15.7 | 54 | 0.77 |

| Year | Year class | Age 2 $\left(10^{9}\right)$ | Age 3 $\left(10^{9}\right)$ | Total mort. \% | Total mort Z |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $1986-1987$ | 1984 | 6.3 | 3.1 | 51 | 0.71 |
| $1987-1988$ | 1985 | 10.1 | 0.7 | 93 | 2.67 |
| $1988-1989$ | 1986 | 1.5 | 0.2 | 87 | 2.01 |
| $1989-1990$ | 1987 | 1.8 | 0.7 | 61 | 2.57 |
| $1990-1991$ | 1988 | 2.2 | 1.9 | 14 | 0.15 |
| $1991-1992$ | 1989 | 4.2 | 0.8 | 81 | 1.66 |
| $1992-1993$ | 1990 | 14.0 | 3.0 | 78 | 1.54 |
| $1993-1994$ | 1991 | 18.9 | 5.0 | 74 | 1.33 |
| $1994-1995$ | 1992 | 9.3 | 1.6 | 83 | 1.76 |
| $1995-1996$ | 1993 | 6.5 | 3.3 | 51 | 0.68 |
| $1996-1997$ | 1994 | 10.1 | 3.1 | 69 | 1.18 |
| $1997-1998$ | 1995 | 7.8 | 4.0 | 49 | 0.67 |
| $1998-1999$ | 1996 | 7.6 | 8.8 | - | - |
| $1999-2000$ | 1997 | 22.8 | 14.6 | 36 | 0.44 |
| $2000-2001$ | 1998 | 20.0 | 12.5 | 38 | 0.47 |

The mortality estimates are unstable during the whole period. Although unstable mortalities may indicate errors in the stock size estimation from year to year, the impression remains that there is a considerable total mortality on young polar cod. Prior to 1993, these mortality estimates represent natural mortality only, as practically no fishing took place. In the period 1993 to 1997 the Russian fleet landed between 5000 and 50000 tonnes of polar cod, in 1998 the catch was negligible. In 1999 the catch was about 20000 tonnes and 35000 tonnes in 2000. Since there has been a minimum landing size of 15 cm (from 1998, 13 cm ) in that fishery, a considerable amount of this could consist of two- and even one-year-olds, and this may explain some, but only a small part of the high total mortality.

## Herring

## Coverage and geographical distribution

The area of distribution of young herring was probably only partly covered. The main registration of the one- to -three-year-old fish was observed in the southern part of the

Barents Sea (Fig. 20). The south-western border of its distribution was not determined due to deficit of time and since herring is not among the target species in this survey. Northwards herring were distributed up to $76^{\circ} 00 \mathrm{~N}$, which is unusual for the herring autumn distribution.

## Abundance estimate

Traditionally an acoustic survey of the young herring is conducted in May, when herring behaviour is more near ideal. September is not a good time for young herring survey because in that season, herring are migrating to the wintering area and are distributed in the surface layer of sea. In addition, the presence of 0 -group herring during autumn may cause difficulties when distributing $\mathrm{s}_{\mathrm{A}}$-values on age groups of herring. For these reasons, the stock size estimates obtained during the autumn may be unrealistic, but may indicate the relative strength of the year classes. Therefore, it was decided to present a stock size estimate for 12 - and 3-group herring as an additional source of information to that obtained during the May survey.

The stock abundance estimate by age, number, and weight was calculated using the same computer program as for capelin. Echo densities were converted to absolute numbers using the following TS-relation:

$$
T S=10 \cdot \log \left(\frac{\sigma}{4 \pi}\right)=20.0 \cdot \log L-71.9
$$

corresponding to a $\sigma$-value of $8.1 \cdot 10^{-7} \cdot L^{2.00}$

The total amount of the estimated part of the young herring was 12.8 billion specimens (Table 5). One-year-old fish constituted 0.5 billion specimens, two-year-old fish 10.5 billion specimens, and three-year-old fish 1.7 billion specimens. The total biomass of young herring amounted to 776000 tonnes, a decrease of about $20 \%$ from last years autumn survey. The estimates of one- and two-year-olds were somewhat higher than those obtained during the Russian survey in May 2001, while the estimate of the three-year-olds was considerably lower. This estimate of the 1998 year class confirms, however, that the size of this year class may be considerably lower than estimated during May 2000. The 0 -group herring was estimated at 24.3 billion individuals, with a mean weight of 5.4 g .

## Blue whiting

In the south-western parts of the Barents Sea young blue whiting were observed in considerable amounts, more than $50 \%$ belonged to the 2000 year class. A quantitative estimation was not attempted since only a small area of the total distribution area of this species was covered. The geographical distribution of blue whiting inside the surveyed area is shown in figure 21.

## Hydrographical conditions

Temperature charts in $0,50,100,200 \mathrm{~m}$, and bottom depths are shown in Figs. 22-26. In September the cooling of surface waters has begun in the north of the Barents Sea because of earlier and more intensive decrease of air temperature there for this period. From August to September the surface temperature decreased by on average $0.5-1.0^{\circ} \mathrm{C}$. However, it increased (by $0.5^{\circ} \mathrm{C}$ ) in the southwest of the sea, where heating continued. The thickness of the upper mixed layer was mainly about $15-25 \mathrm{~m}$ in the east of the region and about $5-10 \mathrm{~m}$ in the southeastern and northern parts.

The maximum horizontal temperature gradients $\left(0.2^{\circ} \mathrm{C}\right.$ per nautical mile) were observed in the western part of the sea in the Polar Front at 50 m depth. This area of the frontal zone had sharper gradients than the other ones, for example, than the central one. Here the gradient was more eroded. A sharpened frontal zone was also found at the same depth near Novaja Zemlja (Coastal Branch of Novaja Zemlja current).

The surface water temperature was on average $1.5^{\circ} \mathrm{C}$ higher than the long-term mean in the western and southern parts of the region and $2.7^{\circ} \mathrm{C}$ in the eastern part.The maximum positive anomalies (up to $+3.0^{\circ} \mathrm{C}$ ) were observed in the east of the Barents Sea (Novaja Zemlja current and its branches). The bottom temperature was close to normal. The surface water temperature differences between 2001 and 2000 were on average $+1.0^{\circ} \mathrm{C}$ for the western, central and eastern, $+2.0^{\circ} \mathrm{C}$ for the northern, and $-0.7^{\circ} \mathrm{C}$ for the southern parts of the area. The bottom temperature was the same as last year except for the south of the sea, where it was on average $1.0^{\circ} \mathrm{C}$ lower.

## Acoustic experiments

During the first part of the survey, some acoustic experiments were undertaken on board "Johan Hjort". The BAB (Bergen Acoustic Buoy) was deployed at two instances in areas of clean capelin registrations, and the reactions of the capelin were observed when "Johan Hjort" approached and passed the buoy at short distance. By visual inspection of the echograms from the buoy echo sounder, it was not possible to detect any reaction even when the depth of the capelin registrations was only 20 m , during neither daytime nor nighttime. However, calculations of volume backscattering from various depths may show slight reactions not visible on the echograms. The results from these experiments will be presented at the acoustic symposium in Montpellier, France, in June 2002.

Figure 9 Echogram showing a typical distribution of adult capelin densely packed near bottom in areas where humpback whales were present. Echogram recorded at $79^{\circ} 18^{\prime} \mathrm{N}-33^{\circ} 00^{\prime} \mathrm{E}$ at 1 . October 2001. Depth is 223 m .

Figure 10 Echogram showing adult capelin distributed in typical schools at all depths, and mixed with polar cod in deeper water. A multisampler haul gave a mixture of polar cod and capelin (50/50) at 180 m and at 110 m , and capelin at $30-50 \mathrm{~m}$. Recorded at $78^{\circ} 29^{\prime} \mathrm{N}-38^{\circ} 58^{\prime} \mathrm{E}$ at 28 September 2001 07:00.08:20 UTC.
